## Abstract

In this paper we investigate the problem of selecting the best logistic population from  $k(\geq 2)$  possible candidates. The selected population must also be better than a given control. We employ the empirical Bayes approach and develop a selection procedure. The performance (rate of convergence) of the proposed selection rule is also analyzed. We also carry out a simulation study to investigate the rate of convergence of the proposed empirical Bayes selection procedure. The results of simulation are provided in the paper.

AMS Classification: primary 62F07; secondary 62C12.

Keywords: Asymptotically optimal; empirical Bayes; selection procedure; logistic population; rate of convergence.

# 1 Introduction

Consider  $k$  independent logistic populations  $\Pi_1, \dots, \Pi_k$  with unknown means  $\theta_1, \dots, \theta_k$ . Let  $\theta_{[1]} \leq \dots \leq \theta_{[k]}$  denote the ordered values of the parameters  $\theta_1, \dots, \theta_k$ . It is assumed that the exact pairing between the ordered and the unordered parameters is unknown. A population  $\Pi_i$  with  $\theta_i = \theta_{[k]}$  is called the best among the  $k$  underlying populations. In many practical situations, we may not only be interested in the selection of the best population, but also require the selected population to be good enough compared with a given control. The problem of selecting the best population has been studied by many researchers. Gupta and Panchapakesan (1996) provided a comprehensive review of the development in this area. It should be pointed out that the logistic distribution serves as a statistical model in many practical situations, see, for example, Balakrishnan (1992). The statistical selection problem for logistic populations has been studied in Gupta and Han (1991, 1992), among others.

In this paper, we employ the empirical Bayes approach to select the best logistic population provided it is also as good as a given control. We describe the formulation of the selection problem and derive a Bayes selection procedure in Section 2. In Section 3, we construct an empirical Bayes selection procedure. Then we investigate the asymptotic optimality of the proposed empirical Bayes selection procedure in Section 4. A simulation study is carried out to investigate the performance of the proposed selection procedure in Section 5.

# 2 Formulation of the Selection Problem

Let  $\Pi_1, \dots, \Pi_k$  be  $k$  independent logistic populations with unknown means  $\theta_1, \dots, \theta_k$ . Let  $\theta_{[1]} \leq \dots \leq \theta_{[k]}$  denote the ordered values of the parameters  $\theta_1, \dots, \theta_k$ . It is assumed that the exact pairing between the ordered and the unordered parameters is unknown. A population  $\pi_i$  with  $\theta_i = \theta_{[k]}$  is considered as the best population. For a given control  $\theta_0$ , population  $\pi_i$  is defined to be good if the corresponding  $\theta_i > \theta_0$ , and bad otherwise. Our goal is to select a population which is the best among the  $k$  populations and also good compared with the standard  $\theta_0$ . If there is no such treatment, we select none.

Let  $\Omega = \{\theta = (\theta_1, \dots, \theta_k)\}$  be the parameter space. Let  $\underline{a} = (a_0, \dots, a_k)$  be an action, where  $a_i = 0, 1; i = 0, 1, \dots, k$  and  $\sum_{i=0}^k a_i = 1$ . For each  $i = 1, \dots, k$ ,  $a_i = 1$  means that population  $\pi_i$  is selected as the best and also considered to be good compared with  $\theta_0$ .  $a_0 = 1$  means that all the  $k$  populations are excluded as bad and none is selected. We consider the loss function

$$L(\underline{\theta}, \underline{a}) = \max(\theta_{[k]}, \theta_0) - \sum_{i=0}^k a_i \theta_i.$$

It is the absolute error loss.

For each  $i = 1, \dots, k$ , let  $X_{i1}, \dots, X_{iM}$  be a sample of size  $M$  from the logistic population  $\Pi_i = L(\theta_i, \sigma_i^2)$  which has unknown mean  $\theta_i$  and unknown variance  $(\pi^2 \sigma_i^2)/3$ , that is, the conditional density distribution of  $X_{ij}$  given  $\theta_i$  and  $\sigma_i^2$  is

$$\frac{1}{\sigma_i} \frac{e^{-(x_i - \theta_i)/\sigma_i}}{(1 + e^{-(x_i - \theta_i)/\sigma_i})^2}, \quad -\infty < x_i < \infty. \quad (1)$$

Since logistic distribution is symmetric about its mean, the mean and the median of a logistic population distribution are identical. For convenience, suppose  $M$  is an odd number, and we denote  $M = 2s + 1$ . We also assume that the unknown population median (and also the mean)  $\theta_i$  has a normal  $N(\mu_i, \tau_i^2)$  prior distribution with unknown parameters  $(\mu_i, \tau_i^2)$ . The random variables  $\theta_1, \dots, \theta_k$  are assumed to be mutually independent. Define  $X_i$  to be the median of  $\{X_{i1}, \dots, X_{iM}\}$ ,  $i = 1, \dots, k$ . Let  $f_i(x_i|\theta_i, \sigma_i^2)$  and  $h_i(\theta_i|\mu_i, \tau_i^2)$  be the conditional distributions of  $X_i$  given  $(\theta_i, \sigma_i^2)$  and  $\theta_i$  given  $(\mu_i, \tau_i^2)$ , respectively. We have, for  $i = 1, \dots, k$ ,

$$f_i(x_i|\theta_i, \sigma_i^2) = \frac{(2s+1)!}{(s!)^2} \frac{1}{\sigma_i} \frac{(e^{-(x_i - \theta_i)/\sigma_i})^{s+1}}{(1 + e^{-(x_i - \theta_i)/\sigma_i})^{2s+2}}, \quad -\infty < x_i < \infty. \quad (2)$$

From (2) we see that the density function  $f_i(x_i|\theta_i, \sigma_i^2)$  is symmetric about  $\theta_i$  given  $\theta_i$ , therefore,

$$EX_i = E(E(X_i|\theta_i)) = E\theta_i = \mu_i. \quad (3)$$

The posterior density of  $\theta_i$  given  $X_i = x_i$  is proportional to

$$\frac{(e^{-(x_i - \theta_i)/\sigma_i})^{s+1}}{(1 + e^{-(x_i - \theta_i)/\sigma_i})^{2s+2}} \cdot e^{-\frac{(\theta_i - \mu_i)^2}{2\tau_i^2}}, \quad -\infty < \theta_i < \infty. \quad (4)$$

Let  $\underline{X} = (X_1, \dots, X_k)$  and  $\mathcal{X}$  be the sample space generated by  $\underline{X}$ . A selection procedure  $\underline{d} = (d_0, \dots, d_k)$  is a mapping defined on the sample space  $\mathcal{X}$ . For every  $\underline{x} \in \mathcal{X}$ ,  $d_i(\underline{x})$ ,  $i = 1, \dots, k$ , is the probability of selecting population  $\Pi_i$  as the best among the  $k$

populations and also good compared with the given control  $\theta_0$ ,  $d_0(\underline{x})$  is the probability of excluding all  $k$  populations as bad and selecting none. Also,  $\sum_{i=0}^k d_i(\underline{x}) = 1$ , for all  $\underline{x} \in \mathcal{X}$ .

Under the absolute error loss, the posterior median is the Bayes estimator of  $\theta_i$ . We denote  $\varphi_i(x_i)$  to be the posterior median of  $\theta_i$  given  $X_i = x_i$ ,  $i = 1, \dots, k$ .

Under the preceding statistical model, the Bayes risk of the selection procedure  $\underline{d}$  is denoted by  $R(\underline{d})$ . We have

$$R(\underline{d}) = - \int_{\mathcal{X}} \left[ \sum_{i=0}^k d_i(\underline{x}) \varphi_i(x_i) \right] f(\underline{x}) d(\underline{x}) + C, \quad (5)$$

where

$$C = \int_{\Omega} \max(\theta_{[k]}, \theta_0) dH(\underline{\theta}),$$

$$H(\underline{\theta}): \text{ the joint distribution of } \underline{\theta} = (\theta_1, \dots, \theta_k),$$

$$f_i(x_i) = \int_{\mathcal{R}} f_i(x_i | \theta_i, \sigma_i^2) h_i(\theta_i | \mu_i, \tau_i^2) d\theta_i,$$

$$f(\underline{x}) = \prod_{i=1}^k f_i(x_i),$$

$$\varphi_0(x_0) = \theta_0.$$

For each  $\underline{x} \in \mathcal{X}$ , let  $I(\underline{x}) = \{i | \varphi_i(x_i) = \max_{0 \leq j \leq k} \varphi_j(x_j), i = 0, 1, \dots, k\}$ , and  $i^* = \min\{i | i \in I(\underline{x})\}$ . Then a Bayes selection procedure  $d^B(\underline{x}) = (d_0^B(\underline{x}), \dots, d_k^B(\underline{x}))$  is given as follows:

$$\begin{cases} d_{i^*}^B(\underline{x}) = 1, \\ d_j^B(\underline{x}) = 0, \quad \text{for } j \neq i^*. \end{cases} \quad (6)$$

### 3 The empirical Bayes Framework

The Bayes selection procedure  $d^B(\underline{x})$  defined in Section 2 depends on the unknown parameters  $(\mu_i, \tau_i^2)$ ,  $i = 1, \dots, k$  and the specific form of  $\varphi_i(x_i)$ . Since the parameters and the specific form of  $\varphi_i(x_i)$  are both unknown, it is impossible to implement the Bayes selection procedure for the selection problem in practice. In the empirical Bayes framework, it is generally assumed that there are some past observations when the present selection is to be made. At time  $l = 1, \dots, n$ , let  $X_{ijl}$  be the  $j$ -th observation from  $\Pi_i$ , that is, for each  $i = 1, \dots, k$ , let

$$\theta_{il} \sim N(\mu_i, \tau_i^2), \quad l = 1, \dots, n, \quad (7)$$

and

$$X_{ijl} \sim L(\theta_{il}, \sigma_i^2), \quad j = 1, \dots, M. \quad (8)$$

For  $l = 1, \dots, n$ , denote  $X_{i,l}$  to be the median of  $(X_{i1l}, \dots, X_{iMl})$ , and

$$X_i(n) = \frac{1}{n} \sum_{l=1}^n X_{i,l}, \quad (9)$$

$$S_i^2(n) = \frac{1}{n-1} \sum_{l=1}^n (X_{i,l} - X_i(n))^2. \quad (10)$$

Then,

$$E(X_{i,l}) = E(E(X_{i,l}|\theta_{il})) = E(\theta_{il}) = \mu_i, \quad (11)$$

and

$$\begin{aligned} \text{Var}(X_{i,l}) &= \text{Var}(E(X_{i,l}|\theta_{il})) + E(\text{Var}(X_{i,l}|\theta_{il})) \\ &= \text{Var}(\theta_{il}) + E(\text{Var}(X_{i,l}|\theta_{il})) \\ &= \tau_i^2 + E(\text{Var}(X_{i,l}|\theta_{il})) \\ &< \infty. \end{aligned} \quad (12)$$

Denote  $\nu_i^2 = \text{Var}(X_{i,l})$ . Since  $(X_{i1}, \dots, X_{in})$  are i.i.d., by the strong law of large numbers, we know that as  $n \rightarrow \infty$ ,

$$\begin{cases} X_i(n) \longrightarrow \mu_i, & a.s. \\ S_i^2(n) \longrightarrow \nu_i^2, & a.s. \end{cases} \quad (13)$$

To derive the empirical Bayes selection procedure, we first consider the following lemmas. The following lemma is from Serfling (1980).

**Lemma 3.1** Let  $\{Y_i, 1 \leq i \leq m\}$  be  $m$  i.i.d. random observations from continuous distribution function  $F$ ; also let  $\hat{\xi}$  and  $\xi$  be the medians of  $\{Y_i, 1 \leq i \leq m\}$  and  $F$ , respectively. Then, for any  $\epsilon > 0$ ,

$$P\{|\hat{\xi} - \xi| > \epsilon\} \leq 2e^{-2m\delta_\epsilon^2}, \quad (14)$$

where  $\delta_\epsilon = \min\{F(\xi + \epsilon) - \frac{1}{2}, \frac{1}{2} - F(\xi - \epsilon)\}$ .

Put  $\sigma' = \min_{1 \leq i \leq k} \sigma_i$ ,  $\sigma^* = \max_{1 \leq i \leq k} \sigma_i$ .  $X_{i1}, \dots, X_{iM}$  are i.i.d. from  $L(\theta_i, \sigma_i^2)$ , which has the following cumulative distribution function

$$F(t_i) = \frac{1}{1 + e^{-(t_i - \theta_i)/\sigma_i}} \quad -\infty < t_i < \infty, \quad (15)$$

and for  $0 < \epsilon \leq \sigma'$ ,

$$F(\theta_i + \epsilon) - \frac{1}{2} = \frac{1}{2} - F(\theta_i - \epsilon) = \frac{e^{\epsilon/\sigma_i} - 1}{2(e^{\epsilon/\sigma_i} + 1)} \geq \frac{\epsilon}{2(e + 1)\sigma^*}. \quad (16)$$

Given  $\theta_i$ ,  $\theta_i$  and  $X_i$  are the population median and sample median respectively, we have, from Lemma 3.1,

$$P\{|X_i - \theta_i| > \epsilon\} \leq 2e^{\frac{-(2s+1)\epsilon^2}{2(e+1)^2\sigma^{*2}}}. \quad (17)$$

For any  $0 < \epsilon \leq \sigma'$ , denote  $S_i = \{\mathbf{x} \in \mathcal{X} : |x_i - \theta_i| \leq \epsilon\}$ . We show that the conditional density of  $X_i$  given  $\theta_i$  and  $\sigma_i^2$  is approximately  $N(\theta_i, \frac{2}{s+1}\sigma_i^2)$  as  $s \rightarrow \infty$ .

From (2), the conditional density of  $X_i$  given  $\theta_i$  and  $\sigma_i^2$  is

$$\begin{aligned} f_i(x_i|\theta_i, \sigma_i^2) &= \frac{(2s+1)!}{(s!)^2} \frac{1}{\sigma_i} \frac{(e^{-(x_i - \theta_i)/\sigma_i})^{s+1}}{(1 + e^{-(x_i - \theta_i)/\sigma_i})^{2s+2}} \\ &= \frac{(2s+1)!}{(s!)^2} \frac{1}{\sigma_i} \frac{1}{(2 + e^{-(x_i - \theta_i)/\sigma_i} + e^{(x_i - \theta_i)/\sigma_i})^{s+1}}. \end{aligned} \quad (18)$$

By Stirling's formula, when  $s$  is large enough,

$$\frac{(2s+1)!}{(s!)^2} \approx \frac{2^{(2s+\frac{3}{2})}}{\sqrt{2\pi}} \sqrt{s+1}. \quad (19)$$

Also choosing  $\epsilon = \epsilon_s \downarrow 0$  to be a sequence of fixed numbers which tend to 0 as  $s \rightarrow \infty$ , by Taylor's polynomial expansion, we have

$$\log(2 + e^{-(x_i - \theta_i)/\sigma_i} + e^{(x_i - \theta_i)/\sigma_i}) \approx \log 4 + \frac{1}{4} \frac{(x_i - \theta_i)^2}{\sigma_i^2} \quad (20)$$

on  $S_i$ . When  $s \rightarrow \infty$ , from (17),

$$P\{X \notin S_i\} \leq 2e^{\frac{-(2s+1)\epsilon^2}{2(e+1)^2\sigma_i^2}} \rightarrow 0. \quad (21)$$

Therefore, we see that as  $s \rightarrow \infty$ ,

$$f_i(x_i|\theta_i, \sigma_i^2) \approx \frac{1}{\sqrt{2\pi}\sqrt{2/s+1}} \frac{1}{\sigma_i} e^{-\frac{s+1}{4} \frac{(x_i - \theta_i)^2}{\sigma_i^2}}, \quad (22)$$

that is,  $f_i(x_i|\theta_i, \sigma_i^2)$  is approximately  $N(\theta_i, \frac{2}{s+1}\sigma_i^2)$ .

From above, we can see that for sufficiently large  $s$ , the conditional density of  $X_{i,l}$  is approximately  $N(\theta_i, \frac{2}{s+1}\sigma_i^2)$ , given  $\theta_i$  and  $\sigma_i$ . Since the prior distribution of  $\theta_i$  is  $N(\mu_i, \tau_i^2)$ , the unconditional density of  $X_{i,l}$  is approximately  $N(\mu_i, \tau_i^2 + \frac{2}{s+1}\sigma_i^2)$ .

For each population  $\Pi_i$ , let  $W_i^2(n)$  be the measure of the overall sample variation for the past observations. That is,

$$\begin{cases} \bar{X}_{il} = \frac{1}{M} \sum_{j=1}^M X_{ijl}, \\ W_i^2(n) = \frac{1}{(M-1)n} \sum_{j=1}^M \sum_{l=1}^n (X_{ijl} - \bar{X}_{il})^2. \end{cases} \quad (23)$$

Then we define, for  $i = 1, \dots, k$ ,

$$\begin{cases} \hat{\mu}_i = X_i(n), \\ \hat{\sigma}_i^2 = \frac{3}{\pi^2} W_i(n)^2, \\ \hat{\nu}_i^2 = S_i^2(n), \\ \hat{\tau}_i^2 = \max(\hat{\nu}_i^2 - \frac{2}{s+1} \hat{\sigma}_i^2, 0). \end{cases} \quad (24)$$

and

$$\begin{cases} \hat{\varphi}_i(x_i) = \begin{cases} (x_i \hat{\tau}_i^2 + \frac{2\hat{\sigma}_i^2}{s+1} \hat{\mu}_i) / \hat{\nu}_i^2, & \text{if } \hat{\nu}_i^2 - \frac{2}{s+1} \hat{\sigma}_i^2 > 0, \\ \hat{\mu}_i, & \text{if } \hat{\nu}_i^2 - \frac{2}{s+1} \hat{\sigma}_i^2 \leq 0, \end{cases} \\ \hat{\varphi}_0(x_0) = \theta_0. \end{cases} \quad (25)$$

Then for each  $\underline{x} \in \mathcal{X}$ , let  $\hat{I}(\underline{x}) = \{i | \hat{\varphi}_i(x_i) = \max_{0 \leq j \leq k} \hat{\varphi}_j(x_j), i = 0, 1, \dots, k\}$ , and  $\hat{i}^* = \min\{i | i \in \hat{I}(\underline{x})\}$ . We propose the following empirical Bayes selection procedure  $d^{(n,s)}(\underline{x}) = (d_0^{(n,s)}(\underline{x}), \dots, d_k^{(n,s)}(\underline{x}))$  as follows:

$$\begin{cases} d_{\hat{i}^*}^{(n,s)} = 1, \\ d_j^{(n,s)} = 0, \quad \text{for } j \neq \hat{i}^*. \end{cases} \quad (26)$$

## 4 Performance of the proposed selection procedure

Consider the empirical Bayes selection procedure  $d^{(n,s)}(\underline{x})$  constructed in Section 3. Let  $R(d^{(n,s)}(\underline{x}))$  be the conditional Bayes risk given the past observations  $\{X_{ijl}, i = 1, \dots, k; j = 1, \dots, M; \text{ and } l = 1, \dots, n\}$  and  $ER(d^{(n,s)}(\underline{x}))$  the Bayes risk of the empirical Bayes selection procedure respectively, where  $E$  is the expectation taken with respect to the past observations  $\{X_{ijl}\}$ . From (5),

$$R(d^{(n,s)}(\underline{x})) = - \int_{\mathcal{X}} \left[ \sum_{i=0}^k d_i^{(n,s)}(\underline{x}) \hat{\varphi}_i(x_i) \right] f(\underline{x}) d(\underline{x}) + C. \quad (27)$$

Note that  $R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x})) \geq 0$ , since  $d^B(\underline{x})$  is the Bayes selection procedure. Therefore,  $E(R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x}))) \geq 0$ . We use the nonnegative difference regret risk  $E(R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x}))) \geq 0$  as a measure of the performance of the selection procedure  $d^{(n,s)}(\underline{x})$ .

We first state some facts about  $\varphi_i(x_i)$ , the posterior median of  $\theta_i$  given  $X_i = x_i$  and  $\mu_i$ . From the definition of  $\varphi_i(x_i)$ , we can see that  $\varphi_i(x_i)$  is between  $x_i$  and  $\mu_i$ . Besides,

**Lemma 4.1** When  $s$  is large enough, for  $1 \leq i \leq k$ ,

$$|\varphi_i(x_i) - x_i| \leq 2\sigma_i \sqrt{\frac{\log s}{s}} \quad (28)$$

**Proof.** We only prove  $\varphi_i(x_i) \leq x_i + 2\sigma_i\sqrt{\frac{\log s}{s}}$  here. The proof of  $\varphi_i(x_i) \geq x_i - 2\sigma_i\sqrt{\frac{\log s}{s}}$  is similar. To prove  $\varphi_i(x_i) \leq x_i + 2\sigma_i\sqrt{\frac{\log s}{s}}$ , it suffices to show that

$$\begin{aligned} & \int_{x_i+2\sigma_i\sqrt{\frac{\log s}{s}}}^{\infty} f_i(x_i|\theta_i, \sigma_i^2) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\ &= \int_{x_i+2\sigma_i\sqrt{\frac{\log s}{s}}}^{\infty} \frac{(2s+1)!}{(s!)^2} \frac{1}{\sigma_i} \frac{1}{\sqrt{2\pi\tau_i}} \frac{(e^{(\theta_i-x_i)/\sigma_i})^{s+1}}{(1+e^{(\theta_i-x_i)/\sigma_i})^{2s+2}} \cdot e^{-\frac{(\theta_i-\mu_i)^2}{2\tau_i^2}} d\theta_i \\ &= \int_{2\sqrt{\frac{\log s}{s}}}^{\infty} \frac{1}{\sqrt{2\pi\tau_i}} \frac{(2s+1)!}{(s!)^2} \left(\frac{e^\theta}{(1+e^\theta)^2}\right)^{s+1} \cdot e^{-\frac{(\sigma_i\theta+x_i-\mu_i)^2}{2\tau_i^2}} d\theta \longrightarrow 0, \end{aligned} \quad (29)$$

as  $s \rightarrow \infty$ . We first show

$$t(\theta, s) := \frac{(2s+1)!}{(s!)^2} \left(\frac{e^\theta}{(1+e^\theta)^2}\right)^{s+1} \longrightarrow 0 \quad \text{as } s \rightarrow \infty, \quad (30)$$

uniformly for  $\theta \geq 2\sqrt{\frac{\log s}{s}}$ . Obviously it is enough to consider the case of  $\theta = 2\sqrt{\frac{\log s}{s}}$  since  $t(\theta, s)$  is decreasing on  $\theta > 0$ . When  $\theta = 2\sqrt{\frac{\log s}{s}}$  and  $s$  is large enough, by Taylor's formula,

$$\log(1+e^\theta) = \log 2 + \frac{1}{2}\theta + \frac{1}{8}\theta^2 + o(\theta^2), \quad (31)$$

and by (19), when  $s$  is large enough,

$$\log \frac{(2s+1)!}{(s!)^2} \leq 2(s+1) \log 2 + \frac{1}{2} \log(s+1). \quad (32)$$

From (31) and (32), we obtain that

$$\begin{aligned} & \log t(\theta, s) \\ &= (s+1)[\theta - 2\log(1+e^\theta)] + \log \frac{(2s+1)!}{(s!)^2} \\ &\leq -2(s+1) \log 2 - \frac{s+1}{4}\theta^2 + 2(s+1) \log 2 + \frac{1}{2} \log s + o(s\theta^2) \\ &= -\left(\frac{s+1}{s} - \frac{1}{2}\right) \log s + o(\log s) \longrightarrow -\infty, \end{aligned} \quad (33)$$

as  $s \rightarrow \infty$ . Therefore, (30) is proved, from which we can immediately see that (29) holds true. It completes the proof of Lemma 4.1.

The next lemma is well known and can be found in Baum and Katz (1965).

**Lemma 4.2** Let  $X_1, \dots, X_n$  be i.i.d. random variables with mean 0. Suppose for  $\alpha > 1$ ,  $E|X_i|^\alpha < \infty$ , for  $i = 1, \dots, n$ , then for any  $\epsilon > 0$ ,

$$P\left\{\left|\sum_{i=1}^n X_i/n\right| \geq \epsilon\right\} = o(n^{-(\alpha-1)}). \quad (34)$$

As a consequence of Lemma 4.2, we have

**Lemma 4.3** Let  $X_1, \dots, X_n$  be independent random variables, with mean  $EX_i = \mu$  and variance  $\text{Var}X_i = \sigma^2$ , for  $i = 1, \dots, n$ . Also let  $\bar{X} = \frac{1}{n} \sum X_i$  and  $S_n^2 = \frac{1}{n-1} \sum (X_i - \bar{X})^2$ . Suppose for  $i = 1, \dots, n$  and a fixed number  $\alpha > 2$ ,  $E|X_i|^\alpha < \infty$ , then for any  $\epsilon > 0$ ,

$$P\{|S_n^2 - \sigma^2| \geq \epsilon\} = o(n^{-(\alpha/2-1)}). \quad (35)$$

The proof of Lemma 4.3 can be found in Gupta and Lin (1997).

Since  $EX_{i,l}^4 < \infty$ , for any  $\epsilon > 0$ , by Lemma 4.2,

$$P\{|\hat{\mu}_i - \mu_i| \geq \epsilon\} = o(n^{-3}), \quad (36)$$

also by Lemma 4.3,

$$P\{|\hat{\nu}_i^2 - \nu_i^2| \geq \epsilon\} = o(n^{-1}). \quad (37)$$

Similarly, we have for any  $\epsilon > 0$ ,

$$P\{|\hat{\sigma}_i^2 - \sigma_i^2| \geq \epsilon\} = o(n^{-1}). \quad (38)$$

When  $s$  is large enough,  $\nu_i^2 - \frac{2}{s+1}\sigma_i^2 > 0$ . Therefore, from (37) and (38), when  $s$  is sufficiently large,

$$P\{\hat{\nu}_i^2 - \frac{2}{s+1}\hat{\sigma}_i^2 \leq 0\} = o(n^{-1}). \quad (39)$$

Besides,  $\tau_i^2 = \nu_i^2 - E(\text{Var}(X_{i,l}|\theta_i))$  by (12) and

$$\begin{aligned} E(\text{Var}(X_{i,l}|\theta_i)) &= \int_{-\infty}^{\infty} (x_{il} - \theta_i)^2 \frac{(2s+1)!}{(s!)^2} \frac{1}{\sigma_i} \frac{(e^{-(x_{il}-\theta_i)/\sigma_i})^{s+1}}{(1 + e^{-(x_{il}-\theta_i)/\sigma_i})^{2s+2}} dx_{il} \\ &= \sigma_i \int_{-\infty}^{\infty} x^2 \frac{(2s+1)!}{(s!)^2} \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx. \end{aligned} \quad (40)$$

We have

**Lemma 4.4**

$$\int_{-\infty}^{\infty} x^2 \frac{(2s+1)!}{(s!)^2} \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx = o\left(\sqrt{\frac{\log s}{s}}\right). \quad (41)$$

**Proof.**

$$\begin{aligned} & \int_{-\infty}^{\infty} x^2 \frac{(2s+1)!}{(s!)^2} \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx \\ &= 2 \int_0^{\infty} x^2 \frac{(2s+1)!}{(s!)^2} \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx \\ &= 2 \left( \int_0^{\sqrt{8\frac{\log s}{s}}} + \int_{\sqrt{8\frac{\log s}{s}}}^3 + \int_3^{\infty} \right) x^2 \frac{(2s+1)!}{(s!)^2} \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx \\ &:= T_1 + T_2 + T_3. \end{aligned} \quad (42)$$

By Stirling's formula, when  $s$  is large enough,

$$\begin{aligned} T_1 &= 2 \frac{(2s+1)!}{(s!)^2} \int_0^{\sqrt{8\frac{\log s}{s}}} x^2 \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx \\ &\leq 2 \cdot 2^{2(s+1)} \sqrt{s+1} \cdot 2^{-2(s+1)} \int_0^{\sqrt{8\frac{\log s}{s}}} x^2 dx \\ &\leq \sqrt{s+1} \left( 8 \frac{\log s}{s} \right)^{3/2} \\ &= o\left(\sqrt{\frac{\log s}{s}}\right). \end{aligned} \quad (43)$$

Using the same approach as in the proof of Lemma 4.1, we have

$$T_2 = 2 \frac{(2s+1)!}{(s!)^2} \int_{\sqrt{8\frac{\log s}{s}}}^3 x^2 \left( \frac{e^x}{(1+e^x)^2} \right)^{s+1} dx$$

$$\begin{aligned}
&\leq 2 \frac{(2s+1)!}{(s!)^2} \left( \frac{e^{\sqrt{8 \frac{\log s}{s}}}}{(1 + e^{\sqrt{8 \frac{\log s}{s}}})^2} \right)^{s+1} \int_{\sqrt{8 \frac{\log s}{s}}}^3 x^2 dx \\
&= o\left(\sqrt{\frac{\log s}{s}}\right).
\end{aligned} \tag{44}$$

Moreover,

$$\begin{aligned}
T_3 &= 2 \frac{(2s+1)!}{(s!)^2} \int_3^\infty x^2 \left( \frac{e^x}{(1 + e^x)^2} \right)^{s+1} dx \\
&\leq 2 \frac{(2s+1)!}{(s!)^2} \int_3^\infty x^2 e^{-(s+1)x} dx \\
&= o\left(\sqrt{\frac{\log s}{s}}\right).
\end{aligned} \tag{45}$$

This completes the proof of Lemma 4.4.

From Lemma 4.4, we observe that when  $s$  is sufficiently large,

$$E(\text{Var}(X_{i,l}|\theta_i)) = o\left(\sqrt{\frac{\log s}{s}}\right), \tag{46}$$

and therefore, by (37), (39) and the definition of  $\hat{\tau}_i^2$ , for  $\epsilon \geq c\sqrt{\frac{\log s}{s}}$ , where  $c > 0$ ,

$$P\{|\hat{\tau}_i^2 - \tau_i^2| \geq \epsilon\} = o(n^{-1}), \tag{47}$$

and furthermore,

$$P\{\hat{\nu}_i^2/\hat{\tau}_i^2 \leq \nu_i^2/(2\tau_i^2)\} = o(n^{-1}). \tag{48}$$

Next we investigate the rate of convergence of  $E(R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x})))$ . Let  $P_{n,s}$  be the probability measure generated by the past observations  $X_{ijl}$ ,  $i = 1, \dots, k$ ;  $j = 1, \dots, M$  and  $l = 1, \dots, n$ .

$$\begin{aligned}
&E(R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x}))) \\
&= \sum_{i=0}^k \sum_{j=0}^k \int_{\mathcal{X}} P_{n,s}\{i^* = i, \hat{i}^* = j\} (\varphi_i(x_i) - \varphi_j(x_j)) f(\underline{x}) d\underline{x}
\end{aligned}$$

$$\begin{aligned}
&= \sum_{i=1}^k \int_{\mathcal{X}} P_{n,s} \{i^* = i, \hat{i}^* = 0\} (\varphi_i(x_i) - \theta_0) f(\underline{x}) d\underline{x} \\
&\quad + \sum_{j=1}^k \int_{\mathcal{X}} P_{n,s} \{i^* = 0, \hat{i}^* = j\} (\theta_0 - \varphi_j(x_j)) f(\underline{x}) d\underline{x} \\
&\quad + \sum_{i=1}^k \sum_{j=1}^k \int_{\mathcal{X}} P_{n,s} \{i^* = i, \hat{i}^* = j\} (\varphi_i(x_i) - \varphi_j(x_j)) f(\underline{x}) d\underline{x} \\
&\leq 2 \sum_{i=1}^k \int_R P_{n,s} \{|\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > |\varphi_i(x_i) - \theta_0|\} |\varphi_i(x_i) - \theta_0| f_i(x_i) dx_i \\
&\quad + 2 \sum_{i=1}^k \sum_{j=1}^k \int_{R^2} P_{n,s} \{|\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{|\varphi_i(x_i) - \varphi_j(x_j)|}{2}\} |\varphi_i(x_i) - \varphi_j(x_j)| \\
&\quad \quad \quad \times f_i(x_i) f_j(x_j) dx_i dx_j \\
&:= I_1 + I_2.
\end{aligned} \tag{49}$$

For any  $\epsilon > 0$ , and  $i, j = 1, \dots, k$ , let

$$\begin{cases} \mathcal{X}_i = \{x_i : |\varphi_i(x_i) - \theta_0| \leq \epsilon\}, \\ \mathcal{X}_{ij} = \{(x_i, x_j) : |\varphi_i(x_i) - \varphi_j(x_j)| \leq \epsilon\}. \end{cases} \tag{50}$$

Then we have

$$\begin{aligned}
I_1 &= 2 \sum_{i=1}^k \int_{\mathcal{X}_i} P_{n,s} \{|\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > |\varphi_i(x_i) - \theta_0|\} |\varphi_i(x_i) - \theta_0| f_i(x_i) dx_i \\
&\quad + 2 \sum_{i=1}^k \int_{R - \mathcal{X}_i} P_{n,s} \{|\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > |\varphi_i(x_i) - \theta_0|\} |\varphi_i(x_i) - \theta_0| f_i(x_i) dx_i \\
&\leq 2 \sum_{i=1}^k \int_{\mathcal{X}_i} \epsilon f_i(x_i) dx_i \\
&\quad + 2 \sum_{i=1}^k \int_R P_{n,s} \{|\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \epsilon\} |\varphi_i(x_i) - \theta_0| f_i(x_i) dx_i.
\end{aligned} \tag{51}$$

By Lemma 4.1, when  $s$  is large enough,  $|\varphi_i(x_i) - x_i| \leq 2\sigma_i \sqrt{\frac{\log s}{s}}$ . From now on, we always set  $\epsilon = 16\sigma^* \sqrt{\frac{\log s}{s}}$ . Therefore, for sufficiently large  $s$ ,

$$|x_i - \theta_0| \leq |\varphi_i(x_i) - x_i| + |\varphi_i(x_i) - \theta_0| \leq 2\epsilon \tag{52}$$

on  $\mathcal{X}_i$  and

$$\begin{aligned}
\int_{\mathcal{X}_i} f_i(x_i) dx_i &\leq \int_{\{|x_i - \theta_0| \leq 2\epsilon\}} f_i(x_i) dx_i \\
&\leq \int_{\{|x_i - \theta_0| \leq 2\epsilon\}} \frac{1}{\sqrt{2\pi\tau_i}} dx_i \\
&= \frac{4\epsilon}{\sqrt{2\pi\tau_i}}.
\end{aligned} \tag{53}$$

Thus,

$$\begin{aligned}
I_1 &\leq \frac{8k}{\sqrt{2\pi\tau_i}} \epsilon^2 \\
&\quad + 2 \sum_{i=1}^k \int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \epsilon \} [|\varphi_i(x_i) - \mu_i| + |\mu_i - \theta_0|] f_i(x_i) dx_i.
\end{aligned} \tag{54}$$

Moreover,

$$\begin{aligned}
I_2 &= 2 \sum_{i=1}^k \sum_{j=1}^k \int_{\mathcal{X}_{ij}} P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{|\varphi_i(x_i) - \varphi_j(x_j)|}{2} \} |\varphi_i(x_i) - \varphi_j(x_j)| \\
&\quad \times f_i(x_i) f_j(x_j) dx_i dx_j \\
&\quad + 2 \sum_{i=1}^k \sum_{j=1}^k \int_{R^2 - \mathcal{X}_{ij}} P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{|\varphi_i(x_i) - \varphi_j(x_j)|}{2} \} |\varphi_i(x_i) - \varphi_j(x_j)| \\
&\quad \times f_i(x_i) f_j(x_j) dx_i dx_j \\
&\leq 2\epsilon \sum_{i=1}^k \sum_{j=1}^k \int_{\mathcal{X}_{ij}} f_i(x_i) f_j(x_j) dx_i dx_j \\
&\quad + 2 \sum_{i=1}^k \sum_{j=1}^k \int_{R^2} P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} |\varphi_i(x_i) - \varphi_j(x_j)| \\
&\quad \times f_i(x_i) f_j(x_j) dx_i dx_j.
\end{aligned} \tag{55}$$

From (28), when  $s$  is large enough,  $|\varphi_i(x_i) - x_i| \leq \epsilon$  and  $|\varphi_j(x_j) - x_j| \leq \epsilon$ . Therefore, when  $s$  is sufficiently large,

$$\{(x_i, x_j) : |\varphi_i(x_i) - \varphi_j(x_j)| \leq \epsilon\} \subset \{(x_i, x_j) : |x_i - x_j| \leq 3\epsilon\}. \tag{56}$$

Thus, similar to (53),

$$\int_{\mathcal{X}_{ij}} f_i(x_i) f_j(x_j) dx_i dx_j \leq \frac{6\epsilon}{\sqrt{2\pi} \min(\tau_i, \tau_j)}. \quad (57)$$

We observe that

$$\begin{aligned} I_2 &\leq \sum_{i=1}^k \sum_{j=1}^k \frac{12\epsilon^2}{\sqrt{2\pi} \min(\tau_i, \tau_j)} \\ &\quad + 2 \sum_{i=1}^k \sum_{j=1}^k \int_{R^2} P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} [|\varphi_i(x_i) - \mu_i| + |\varphi_j(x_j) - \mu_j| \\ &\quad + |\mu_i - \mu_j|] f_i(x_i) f_j(x_j) dx_i dx_j. \end{aligned} \quad (58)$$

From (54) and (58), it suffices to analyze the limiting behaviors of

$$\begin{aligned} &\int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} f_i(x_i) dx_i, \\ &\int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} |\varphi_i(x_i) - \mu_i| f_i(x_i) dx_i. \end{aligned} \quad (59)$$

We first analyze  $\int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} f_i(x_i) dx_i$ . Denote

$$\begin{aligned} \mathcal{Y}_i &= \{x_i : |\varphi_i(x_i) - \theta_i| \leq \frac{\epsilon}{4}\}, \\ \mathcal{Z}_i &= \{x_i : |x_i - \theta_i| \leq \frac{\epsilon}{8}\}. \end{aligned} \quad (60)$$

By Lemma 4.1, we know that when  $s$  is large enough,  $|\varphi_i(x_i) - x_i| \leq \frac{\epsilon}{8}$ . Therefore, for sufficiently large  $s$ , we have

$$R - \mathcal{Y}_i \subset R - \mathcal{Z}_i \quad (61)$$

and

$$\begin{aligned} &\int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} f_i(x_i) dx_i \\ &\leq \int_R \left( \int_{R - \mathcal{Z}_i} P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} f_i(x_i | \theta_i, \sigma_i^2) h_i(\theta_i | \mu_i, \tau_i^2) dx_i \right) d\theta_i \\ &\quad + \int_R \left( \int_{\mathcal{Y}_i} P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} f_i(x_i | \theta_i, \sigma_i^2) h_i(\theta_i | \mu_i, \tau_i^2) dx_i \right) d\theta_i \end{aligned}$$

$$\begin{aligned}
&\leq \int_R \left( \int_{R-Z_i} f_i(x_i|\theta_i, \sigma_i^2) h_i(\theta_i|\mu_i, \tau_i^2) dx_i \right) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \theta_i| \geq \frac{\epsilon}{4} \} f_i(x_i|\theta_i, \sigma_i^2) h_i(\theta_i|\mu_i, \tau_i^2) dx_i \right) d\theta_i \\
&\leq \int_R \left( \int_{|x_i - \theta_i| > \frac{\epsilon}{8}} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \theta_i| \geq \frac{\epsilon}{4}, \hat{\nu}_i^2 - 2\hat{\sigma}_i^2/(s+1) > 0 \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) \\
&\quad \quad \times h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ \hat{\nu}_i^2 - 2\hat{\sigma}_i^2/(s+1) \leq 0 \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\leq 2 \int_R e^{-\frac{(2s+1)\epsilon^2}{128(e+1)^2\sigma_i^{*2}}} h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |(x_i\hat{\tau}_i^2 + \frac{2\hat{\sigma}_i^2}{s+1}\hat{\mu}_i)/\hat{\nu}_i^2 - \theta_i| \geq \frac{\epsilon}{4} \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + o(n^{-1}) \\
&\leq 2e^{-\frac{(2s+1)\epsilon^2}{128(e+1)^2\sigma_i^{*2}}} \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |x_i - \theta_i| \geq \frac{\hat{\nu}_i^2 \epsilon}{\hat{\tau}_i^2 8} \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |\hat{\mu}_i - \theta_i| \geq \frac{(s+1)\hat{\nu}_i^2 \epsilon}{16\hat{\sigma}_i^2} \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + o(n^{-1}) \\
&\leq O(s^{-1}) \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |x_i - \theta_i| \geq \frac{\hat{\nu}_i^2 \epsilon}{\hat{\tau}_i^2 8}, \frac{\hat{\nu}_i^2}{\hat{\tau}_i^2} \geq \nu_i^2/(2\tau_i^2) \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ \frac{\hat{\nu}_i^2}{\hat{\tau}_i^2} \leq \nu_i^2/(2\tau_i^2) \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |\hat{\mu}_i - \theta_i| \geq \frac{(s+1)\hat{\nu}_i^2 \epsilon}{16\hat{\sigma}_i^2}, \hat{\nu}_i^2/\hat{\sigma}_i^2 \geq \nu_i^2/(2\sigma_i^2) \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) \\
&\quad \quad \times h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ \hat{\nu}_i^2/\hat{\sigma}_i^2 \leq \nu_i^2/(2\sigma_i^2) \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + o(n^{-1}) \\
&\leq O(s^{-1}) + \int_R \left( \int_{|x_i - \theta_i| \geq \frac{\nu_i^2}{2\tau_i^2} \frac{\epsilon}{16}} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i + o(n^{-1}) \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |\theta_i - \mu_i| \geq \frac{(s+1)\nu_i^2 \epsilon}{64\sigma_i^2} \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + \int_R \left( \int_R P_{n,s} \{ |\hat{\mu}_i - \mu_i| \geq \frac{(s+1)\nu_i^2 \epsilon}{64\sigma_i^2} \} f_i(x_i|\theta_i, \sigma_i^2) dx_i \right) h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + o(n^{-1}) \\
&\leq O(s^{-1}) + 2e^{-\frac{(2s+1)\nu_i^4 \epsilon^2}{2 \times 32^2 (e+1)^2 \sigma_i^{*2} \tau_i^4}} + \int_{|\theta_i - \mu_i| \geq \frac{(s+1)\nu_i^2 \epsilon}{64\sigma_i^2}} h_i(\theta_i|\mu_i, \tau_i^2) d\theta_i \\
&\quad + o(n^{-3}) + o(n^{-1})
\end{aligned}$$

$$\begin{aligned}
&\leq O(s^{-1}) + e^{-\frac{(s+1)^2 \nu^4 \epsilon^2}{2 \times 64^2 \sigma_i^4 \tau_i^2}} + o(n^{-1}) \\
&= O(s^{-1}) + o(n^{-1}).
\end{aligned} \tag{62}$$

Similarly, we can obtain

$$\int_R P_{n,s} \{ |\hat{\varphi}_i(x_i) - \varphi_i(x_i)| > \frac{\epsilon}{2} \} |\varphi_i(x_i) - \mu_i| f_i(x_i) dx_i = o\left(\frac{1}{n}\right) + O\left(\frac{1}{s}\right). \tag{63}$$

Combining (49), (54), (58), (59), (62) and (63), we finally obtain the rate of convergence of the proposed selection procedure.

**Theorem 1.** The selection procedure  $d(\underline{x})$  defined in (26) is asymptotically optimal with convergence rate of order  $o(\frac{1}{n}) + O(\frac{\log s}{s})$ . That is,

$$E(R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x}))) = o\left(\frac{1}{n}\right) + O\left(\frac{\log s}{s}\right). \tag{64}$$

## 5 Simulations

We carried out a simulation study to investigate the preformance of the selection procedure  $d^{(n,s)}(\underline{x})$ . The expected risk  $E(R(d^{(n,s)}(\underline{x})) - R(d^B(\underline{x})))$  is used as measure of the performance of the selection rule.

We consider the following case in which  $k = 3$ , that is, we have 3 logistic populations  $\Pi_1, \Pi_2$  and  $\Pi_3$  and we would like to use the proposed selection procedure to select the best population compared with a control.

The simulation scheme is described as follows:

(1) For each  $n, s$  and for each  $i = 1, 2, 3$ , generate independent random variables  $X_{i1}, \dots, X_{iM}$  as follows:

$$\left\{ \begin{array}{ll} \text{for } l = 1, \dots, n, \\ \text{(a) first generate } \theta_{il} \text{ from normal distribution with density } N(\mu_i, \tau_i^2) \\ \text{(b) then generate } X_{ijl} \text{ from logistic distribution } L(\theta_{il}, \sigma_i) \end{array} \right. \tag{65}$$

(2) Based on the past observations  $X_{ijl}$ , and the present observations  $\underline{X} = (X_1, \dots, X_k)$ , we construct the empirical Bayes selection procedure  $d^{(n,s)}(\underline{x})$  and compute the conditional difference

$$D = R((d^{(n,s)}(\underline{x}) - R(d^B(\underline{x}))). \quad (66)$$

(3) Repeat steps (1) and (2) 400 times. The average of the conditional differences on the 400 repetitions which is denoted by  $\bar{D}(n, s)$ , is used as an estimator of the differences  $ER((d^{(n,s)}(\underline{x}) - R(d^B(\underline{x})))$ .

Tables (1) gives the simulation results on the performance of the proposed empirical Bayes selection procedures. We choose  $\theta_0 = 0.5$ ,  $\mu_1 = 0.4$ ,  $\mu_2 = 0.5$ , and  $\mu_3 = 0.6$ ,  $\tau_1 = \tau_2 = \tau_3 = 1$ .

From these results, we see that  $\bar{D}(n, s)$  decreases to zero very rapidly. It supports Theorem 1 that the convergence rate is  $o(\frac{1}{n}) + O(\frac{\log s}{s})$ .

Table 1

Performance of the selection rule

13. ABSTRACT (Maximum 200 words) In this paper we investigate the problem of selecting the best logistic population from $k(\geq 2)$ possible candidates. The selected population must also be better than a given control. We employ the empirical Bayes approach and develop a selection procedure. The performance (rate of convergence) of the proposed selection rule is also analyzed. We also carry out a simulation study to investigate the rate of convergence of the proposed empirical Bayes selection procedure. The results of simulation are provided in the paper.
